Suppose we have a very complicated equation to solve and we need to find some mathematical way to solve for  $x$ .

We are given an equation to solve: Find the Roots

$$f(x) = 48x(1+x)^{60}(1+x)^{60} + 1 = 0$$

- An approximate solution
- Let's plot the equation to see where it crosses the  $x$  axis
- Ask: for what value of  $x$  does this  $x$ -axis intersection happen?
- In general, how do we find values of  $x$ ?

# Plot the Equation

Approaching solutions by approximation ...

- The relevant root is labeled  $r$
- First approximation for  $x_1$  is a simple *guess* made by understanding the plot

- Consider the tangent line,  $L$  to the curve  $y = f(x)$  at the point  $(x_1, f(x_1))$  and look at the  $x$ -intercept of  $L$ , labeled  $x_2$ .
- Main idea: the tangent line is close to the curve and its  $x$ -intercept (an intersection point at  $x_2$ ), is close to the  $x$ -intercept of the curve (the root  $r$ ).
- This point root  $r$  that want to find!

Newton's  
Method

Guess the  
root

## The Derivative

1. Choose an interval

2. Find the raw change

$$f'(x) = \lim_{dx \rightarrow 0} \frac{f(x+dx) - f(x)}{dx}$$

4. Make your model perfect

3. Find the rate of change

### Roughly speaking...

- The derivative is an equation extracted from the original  $f(x)$  used to find the  $x$  values of where the  $y = 0$ .

Newton's  
Method

Guess the  
root

Formatting

## Roughly speaking...

- We want to find where line  $L$  passes  $x$ -intercept
- Slope of line  $L$ :  $f'(x)$  (the derivative is tangent to curve)
- Line formula (from algebra):  $y = m * x + b$
- To find a formula for  $x_2$  in terms of  $x_1$

$$y - f(x_1) = f'(x_1)(x_2 - x_1) \quad (1)$$

# Thinking Recursively

Use derivatives to find lines crossing  $x$ -axis, converging on root

Newton's  
Method

Guess the  
root
